㉙ High performance semipermeable composite membrane and process for producing same.

㉚ The invention relates to a high performance semi-permeable composite membrane with (a) a microporous substrate, (b) an intermediate transport layer comprising a crosslinked polymer made from a water soluble polymer formed upon and affixed to said microporous substrate and (c) an ultrathin solute rejection barrier layer.

EP 0 072 002 A1

HIGH PERFORMANCE SEMIPERMEABLE COMPOSITE  
MEMBRANE AND PROCESS FOR PRODUCING SAME

---

- This invention relates to a high performance membrane and a process for producing same, and relates particularly to a novel and high advantageous semipermeable composite membrane having a high percentage solute rejection and
- 05 which is especially useful for production of pure water from seawater, and the recovery of valuable materials, and which has excellent resistance to degradation in the presence of chlorine.
- 10 In recent years liquid separation and purification systems utilizing reverse osmosis have been applied in many fields such as the desalination of seawater or other saline waters and in the recovery of valuable materials from waste liquids of various types.

- 2 -

Various semipermeable membranes are now being used in commercial reverse osmosis treatment of aqueous solutions, either for water purification or for concentration of liquid solutions, or both. Such semipermeable  
05 membranes include the early Loeb type membranes made of cellulose acetate by processes as described in U.S. Patent Nos. 3,133,132 and 3,133,137. The Loeb type membranes are asymmetric types and are characterized by a very thin, dense surface layer  
10 or skin that is supported upon an integrally attached, thicker supporting layer. However, the cellulose acetate Loeb type membranes are restricted as to their use and processability, largely because the membranes must permanently be kept wet; their effectiveness as  
15 reverse osmosis membranes is lost once the membranes are dried.

These membranes have also exhibited deficiencies such as alkaline or acidic degradation and biological  
20 degradations which result in short life. Furthermore, these membranes are not used widely in separation or recovery of valuable materials from liquid mixtures containing organic chemicals, because the membranes have low selectivity for valuable organic materials and  
25 poor resistance to the effects of organic solvents.

Other Loeb type membranes which are also used include membranes fabricated from polyamides (of. eg. US-A-3,567,632), polyamide hydrazide, polyamide acid  
30 (JP-A- 50-121,168), crosslinked polyamide (JP-A-52-152,879), polyimidazopyron, polybenzimidazol,

- 3 -

polysulfonamide, polybenzimidazolone, polyarylene oxide, polyvinyl methyl ether, polyacrylonitrile, polyvinyl alcohol, polyhydroxy ethyl methacrylate, and polyvinylidene chloride, etc.. However, the separation performance and the resistance to chemical degradation of these Loeb type membranes are all inferior to those of the cellulose acetate membranes.

When utilizing semipermeable membranes in the treatment of saline water, particularly the treatment of seawater, it is often necessary to treat the feed water with chlorine, formalin or other disinfectants so as to guard against bacterial growth which could greatly impair the performance of the membranes as a result of fouling or the like. But these synthetic membranes have poor durability when exposed to chlorine, which quickly causes a chemical degradation of the membranes and shortens their useful life, accompanied by very low salt rejection, which results in inefficient operation.

In a later development, processes have been provided for preparing an ultrathin film or skin separately from a porous support layer.

25       Membranes thus prepared have become known as composite membranes. In preparing such membranes it is possible to tailor both the ultrathin film and the porous supporting layer in such a manner that each component possesses the most desirable properties. Processes for  
30       preparing composite membranes are described in US-A-4,277,344, 4,039,440, 4,005,012, 3,744,642 and 3,926,798 and in P.B. Reports Nos. 234,198 and 248,670.

35       Generally, these composite membranes have also exhibited

- 4 -

05 deficiencies such as compaction resulting in short  
life, as well as undesirable low flux or solute  
rejection, having no resistance to chlorine, formalin  
or other disinfectants, all resulting in insufficient  
operation.

10 It is an object of this invention to provide a semi-  
permeable composite reverse osmosis membrane which provides  
excellent solute rejection and has excellent resistance  
to chlorine and formalin.

15 Another object of the invention is to provide a composite  
membrane which is not only capable of producing pure  
water from seawater but is also useful for the recovery  
of valuable materials from the waste water as well. A  
further object of this invention is to provide a method  
for making such a composite membrane which can be  
produced in simple steps and thus lends itself to  
commercial production.

20 Yet another object is to provide a method of controlling  
the membrane thickness of an ultrathin membrane to provide  
membranes of predetermined thickness ideally adaptable  
for usage in a wide variety of pressure conditions in  
25 service.

Other objects and advantages of this invention will appear  
in further detail hereinafter.

30 In accordance with this invention, a semipermeable composite  
membrane is provided comprising a microporous substrate, an

35

- 5 -

intermediate transport layer and an ultrathin solute barrier layer formed on a surface of the microporous substrate. The ultrathin solute barrier layer comprising an inner portion and an outer portion is composed of a crosslinked polymer made by reacting (a) a mixture containing a water-soluble polymer having reactive groups selected from amino and hydroxyl groups, said mixture also containing a monomer having at least two amino groups on an aromatic nucleus comprising 1 to 3 aromatic rings, with (b) a crosslinked agent having acyl halide groups capable of reacting with the reactive groups of the water-soluble polymer and also reacting with the amino groups of the monomer contained in the mixture (a). The solution containing mixture (a) and the solution containing (b) are essentially immiscible with one another whereby interfacial polymerization takes place among the water-soluble polymer, monomer, and the crosslinked agent to form an inner portion of the ultrathin layer. At the same time, some monomer migrates through the inner portion of the ultrathin layer and polymerizes with the crosslinked agent to form a crosslinked polymeric outer portion of the ultrathin layer on the aforementioned inner portion of the ultrathin layer.

25

By causing the polymerization in such an interfacial manner, the resulting polymer forms an ultrathin solute rejection barrier layer of surprising uniformity with respect to thickness. Further, by predetermining the amount and type of monomer present in the aqueous solution, the amount penetrating through the aforesaid inner portion of the ultrathin barrier is also determined, and this predetermines the thickness of the outer

30

35

- 6 -

portion of the ultrathin barrier layer that will be produced from polymerization of the monomer with the crosslinking agent. In this surprising and highly effective manner, the overall thickness of the ultrathin solute rejection barrier layer can be accurately predicted and the uniformity of thickness of the resulting barrier is entirely unprecedented.

Thickness control is highly important because solute rejection barriers are utilized under various pressures in different fields of service. Where low values of solute rejection are sufficient, very thin barriers (100Å or less) may be used at low pressures. On the other hand, barriers as thick as 100Å or more may be provided in accordance with this invention, and these may be used under very high pressure with adequate solute rejection performance.

Examples of water-soluble polymers which are useful in the practice of this invention include amine modified polyepihalohydrin; polyethylene imine, polyepiaminohydrin and polyvinyl alcohol, preferably, water-soluble reaction products which are modified by reacting a polyepihalohydrin represented by the following formula (I) with an amine compound (II):

wherein X is a halogen atom such as Cl, Br or I, and i and j are mole fractions which satisfy the following relations:

- 7 -

$$\begin{aligned}i + j &= 1 \\0,2 < i &\leq 1 \\0 &\leq j < 0.8\end{aligned}$$

05

10    The amine compound (II) which is to be reacted with  
a polyepihalohydrin (I) is a non-cyclic or cyclic  
polyamine containing:

- 15        1) 0 to 1 amino group,  
          2) more than 1 imino group and in which  
          3) the sum of the amino group and the imino groups is  
more than 2, wherein the amino group when present is  
bonded to a carbon atom and the imino groups are bonded  
to a carbon atom or to two different carbon atoms, the  
20    total number of carbon atoms being from 3 to 12.

The monomer which is used with the water-soluble polymer  
in the practice of this invention preferably fulfills the  
following requirements:

25

It is an aromatic polyamine containing at least 2 amino  
groups on an aromatic compound comprising 1 to 3  
aromatic rings.

30    Examples of polyepihalohydrins represented by formula (I)  
include polyepichlorohydrin, polyepibromohydrin and  
polyepiodohydrin. Examples of the monomer include

- 8 -

phenylene diamine, diaminodiphenylether, diamino-diphenylsulfone, diaminodiphenylmethane, tetraamino-diphenylmethane, preferably m-phenylene diamine.

05 These polyepihalohydrins (I) may be modified by reacting  
them with amine compounds (II) according to the procedure  
well known in prior art, for example as described in  
US-A 4,056,510. Examples of the amine compound (II)  
being reacted with the polyepihalohydrins (I) are  
10 monomeric polyamine such as 4-(aminomethyl)piperidine,  
ethylene diamine, diaminopropane, diaminobutane,  
diaminopentane, diethylene triamine, dipropylene triamine,  
triethylene triamine, pentaethylene hexamine and the like,  
preferably 4-(aminomethyl)piperidine.

15 The mixture used for preparing the composite membrane  
of this invention is obtained by mixing the monomer and  
the polymer having amino groups or hydroxyl groups.  
However, an amine modified polyepihalohydrin containing  
20 excess monomeric polyamine may be used to obtain a  
membrane with a wide variety of performance.

The mixing ratio of the polymer with the monomer is about  
10 % to 90 % by weight of monomer in 90 % to 10 % by weight  
25 of polymer, preferably from 20 % to 85 % by weight of  
polymer and about 80 % to 15 % by weight of monomer. When  
the mixing ratio is substantially outside the 90 % - 10 %  
ratio, the resulting composite membrane shows lower solute  
rejection or lower flux.

30 As will be described hereinafter, the semipermeable composite  
membrane of this invention comprises two crosslinked  
polymers, the ultrathin solute barrier is obtained by

35

reacting the mixture with a crosslinking agent and the intermediate transport layer is obtained by heat crosslinking of the water-soluble polymer. Semipermeable composite membranes obtained from the crosslinked  
05 polymers have the fine structure of a two phase system, that is, an ultrathin solute barrier layer and an intermediate transport layer.

It is considered that the ultrathin solute barrier layer  
10 determines the solute rejection or permeability of the composite membrane, and that the intermediate transport layer is the layer adhering the ultrathin solute barrier to the microporous substrate.

15 When a membrane is prepared by using only the monomer and/or the monomeric polyamine, a fine structure attributable to the use of a two phase system does not form in the resulting semipermeable membrane, and the composite membrane does not have good separation  
20 performance. On the other hand, when a membrane is prepared by using only the water-soluble polymer having amino groups or hydroxyl groups (without the monomer or the monomeric polyamine), the membrane formed does have the fine structure of a two phase system, but  
25 the liquid separation performance of the resulting composite membrane is poor. Further, such membranes tend to deteriorate in the course of time, because the solute barrier layer of the semipermeable membrane is very thin and is prone to mechanical damage.

30 The thickness of the ultrathin solute barrier layer and the intermediate transport layer of the membrane may be controlled in a highly effective manner by altering the  
35

05 mixing ratio of the monomer to the water-soluble  
polymer. The performance of the composite membrane  
can be controlled to some degree by altering the  
thickness or the ultrathin solute barrier layer and  
the intermediate transport layer. The thickness of  
the ultrathin solute barrier layer is preferably  
within the range of  $100\text{\AA}$  to about  $1000\text{\AA}$ , more  
preferably from about  $150\text{\AA}$  to  $500\text{\AA}$ , and the thickness  
10 of the intermediate transport layer is preferably in  
the range of about  $100\text{\AA}$  to 3 microns, more preferably  
about  $100\text{\AA}$  to about 2 microns. When the ultrathin  
solute barrier layer is less than about  $100\text{\AA}$  in  
thickness, the composite membrane is prone to mechanical  
damage, and it is difficult to retain the separation  
15 performance of the membrane.

On the other hand, when the ultrathin solute barrier  
layer is thicker than about  $1,000\text{\AA}$  the liquid per-  
meation of the composite membrane decreases. Further-  
20 more, when the thickness of the intermediate transport  
layer is outside the above range, the composite  
membrane has reduced liquid separation performance or  
undergoes a performance change, because the thickness  
of the intermediate transport layer is somewhat prone  
25 to unevenness and irregularity of the surface of the  
microporous substrate.

The sum of the thicknesses of the ultrathin solute  
barrier layer and the intermediate transport layer is  
30 preferably about  $150\text{\AA}$  to about 3 microns.

Figure 1 is an electron microphotograph showing the  
fine structure of an ultrathin cross section of a

semipermeable composite membrane according to one embodiment of the present invention.

05 This figure clearly indicates the fine structure of the membrane surface as examined with the aid of an electron microscope. The membrane surface was shadowed with Pt-Pd and carbon in a vacuum-depositing apparatus. The membrane was embedded with an epoxy resin, dyed with an  $\text{OsO}_4$  solution and was sectioned by using an  
10 ultramicrotome with a diamond knife. The ultrathin membrane layer of approximately  $300\text{\AA}$  thickness and the intermediate transport layer of about  $200\text{\AA}$  thickness were examined by a Hitachi HU-12 Transmission Electron Microscope.

15 Figure 2 is an electron microphotograph similar to Figure 1 showing the fine structure of an ultrathin cross-section of a semipermeable composite membrane obtained by using a solution containing only the amine modified polyepihalohydrin. Figure 2 clearly shows  
20 that the ultrathin membrane layer is approximately  $100\text{\AA}$  in this case. The magnifications of the microphotographs of Figure 1 and 2 are about 90,000 times for each. The microphotographs show that the ultrathin solute barrier layer of the membrane of Figure 1 is  
25 significantly thicker than the ultrathin solute barrier of Figure 2.

30 Figure 3 is a schematic cross-sectional drawing, greatly enlarged, showing further details regarding the nature of the ultrathin solute barrier layer and the manner in which it is formed.

Figure 4 is a schematic drawing similar to Figure 1 but on a less enlarged scale, showing a barrier of this invention in combination with a polysulfone substrate and a fabric.

05

The interfacial polycondensation method, well known as such is used for fabrication of the semipermeable composite membranes of this invention. The method has been described in great detail by P.W. Morgan in  
10 "Condensation Polymers by Interfacial and Solution Methods", Intersciences Publishers, New York, 1965.

15

According to this method, the aqueous mixture of the watersoluble polymer having the reactive groups selected from amino and hydroxyl groups and the monomer is coated on a surface of the microporous substrate; thereafter the hydrophobic solution containing crosslinking agents whose acyl halide groups are capable of reacting with the amino groups or  
20 hydroxyl groups is coated on but does not mix with the aqueous solution and forms a separate layer thereon. In situ interfacial polycondensation on the microporous substrate takes place between the immiscible solutions and produces an ultrathin surface coating possessing  
25 solute barrier characteristics.

30

Examples of a crosslinking agent useful in the practice of this invention are selected from the group consisting of the acid chlorides such as trimesoyl chloride,  
30 trimellitic acid chloride etc.. They are dissolved in suitable solvents which are substantially immiscible with water, such as hexane, heptane, pentane, benzene, carbon tetrachloride, trifluorotrchloroethane, etc..

35

The microporous substrate may be formed as a flat sheet or as a tubular or hollow fibers, or in any other desired shape usually used for reverse osmosis separation processes, and the pores in the surface are preferably sized between about  $10\text{\AA}$  and about  $300\text{\AA}$ . The pores tend to become gradually enlarged toward the back (supporting substrate) side. The aforementioned microporous substrate may be distinguished as an anisotropic membrane made from homopolymers or from blended polymers of polysulfone, chlorinated polyethylene, polyvinyl chloride, cellulose acetate, cellulose nitrate, etc.. The most preferable material is polysulfone. Preparation of a polysulfone substrate is described in "Office of Saline Water Research and Development Progress Report" No. 359, Oct., 1968.

The aforementioned two phase system semipermeable membranes of this invention, composed of an ultrathin solute barrier layer and an intermediate transport layer can be obtained by using an aqueous solution containing the water-soluble polymer having reactive groups selected from amino and hydroxyl groups and the monomer, in which the concentration of the aforementioned polymer is preferably from about 0.1 % to 10 % by weight, more preferably from 0.5 % to 5 % by weight. The concentration of the monomer is preferably within the range of about 0.1 % to 10 % by weight, more preferably about 0.5 % to 5 % by weight. As the result of these concentrations, a two-phase system having the desired thickness is readily and conveniently obtained. From these a composite membrane possessing excellent separation characteristics can be fabricated with good yield. By

simply increasing the monomer content in the solution, the thickness of the resulting ultrathin barrier may also be increased.

5 The water-soluble polymer having the reactive groups selected from amino and hydroxyl groups and the monomer in the aqueous solution are converted to a water-insoluble crosslinked polymer made by interfacial reaction with the crosslinking agent contained in the hydrophilic phase. For this reaction one of a number of alkaline reagents, 0 such as sodium hydroxide, potassium hydroxide, sodium carbonate, sodium bicarbonate, etc. may be added to remove by-products of the reaction, such as hydrogen chloride, etc.. Further, catalysts such as crown ; ethers may be added for acceleration of the reaction. On the other hand, the optimum concentration of the crosslinking agent in the water immiscible solution is affected by the concentration of the water-soluble polymer having amino or hydroxyl groups and the monomer in the 0 aqueous phase. The preferable concentration is between about 0.1 % to 10% by weight.

The microporous substrate covered with the ultrathin solute barrier layer, formed by the interfacial 5 condensation reaction, is cured at a high temperature, which could not be so high as to break the microporous substrate. The temperature is preferably between 80°C and 150°C. As a result of this curing, the intermediate transport layer of water-soluble polymer of the 30 aqueous phase becomes water-insoluble, forming an intermediate transport layer between the ultrathin solute barrier layer and the substrate. The semi-permeable ultrathin composite membrane becomes stabilized as to durability and separation characteristics. The

05 ultrathin solute barrier layer is formed by  
interfacial condensation between the mixture of water-  
soluble polymer having the group selected from amino  
and hydroxyl groups and the monomer, and the  
crosslinking agent.

10 When the water-soluble polymer having the reactive group  
selected from amino and hydroxyl groups is the only  
species in the water solution, the ultrathin solute  
barrier layer formed in the same manner is not more  
than about 100Å in thickness. On the other hand, when  
the monomer is the only species present, the ultrathin  
solute barrier layer attains a maximum thickness of  
only a few microns . Accordingly, the resulting semi-  
15 permeable composite membranes are of only very limited  
use in either case.

20 In view of the nature of the interfacial reaction,  
the monomer size, and the reactivity of the monomer  
and of the water-soluble polymer having amino or  
hydroxyl groups, the inner portion of the ultrathin  
solute barrier layer may be formed immediately after  
contact with the crosslinking agent, accompanied  
or followed by diffusion of the monomer only through  
25 the inner portion of the ultrathin solute barrier layer.  
Having penetrated the inner portion of the ultrathin  
layer, the monomer reacts with the crosslinking agent  
contained in the hydrophobic phase and thus forms  
additional polymer which is deposited upon the inner  
30 portion of the ultrathin solute barrier layer and  
increases its thickness accordingly.

Because of this phenomenon, the resulting thickness of the ultrathin solute barrier layer of this invention is greater than if only the water-soluble polymer having amino groups or hydroxyl groups is used. Also, such layer is thinner and more uniform than one produced by using a monomer only.

The protective layer later applied to the ultrathin solute barrier layer causes the composite membrane to be much more resistant to mechanical shocks. Water-soluble organic polymers such as polyvinyl alcohol (PVA), polyvinyl pyrrolidone, polyacrylamide and polyacrylic acid, for example, are useful for forming the protective layer. Addition of a polyfunctional halogenated compound to this water solution is sometimes useful for crosslinking the protective layer, resulting in good water resistance. The remaining polyfunctional reagents of the interfacial polycondensation on the ultrathin solute barrier layer are also useful for crosslinking the protective layer. The optimum thickness of the protective layer is about 0.1 micron to 20 microns when PVA is used.

Figure 3 of the drawings shows diagrammatically and greatly magnified a typical structure obtained according to this invention. The intermediate transport layer 10 is composed of a water-insoluble polymer formed from the water-soluble polymer of the aqueous layer which remains in place on the polysulfone substrate 11 and which was solidified and rendered water-insoluble by heating. Next to the intermediate transport layer 10 is the composite ultrathin solute rejection barrier 12; its inner layer 13 is formed by

reaction of the water-soluble polymer plus the monomer with the crosslinking agent: a crosslinked product of all three. During these reactions the monomer also migrates in the direction of the arrow in Figure 3 from the aqueous phase through the barrier layer 13 formed at the interface, and reacts with the crosslinking agents of the organic phase, producing the outer layer 14 of the ultrathin solute rejection barrier. This outer layer 14 is the crosslinked product of the monomer with the crosslinking agent. Number 15 designates the outer protective layer preferably applied subsequently.

Figure 4 shows the polysulfone substrate 11 supported by a fabric 16. This figure also shows the typically irregular surface 17 of the polysulfone substrate 11, which is difficult to provide with a thick uniform coating. The intermediate transport layer 10 admirably compensates for this surface roughness and is securely attached to the polysulfone layer while also providing an excellent, much more uniform supporting surface for the ultrathin solute barrier layer 12. In this manner thickness variations of layer 12 are minimized. For example, in a typical case a layer 12 may be provided with a maximum thickness of 500Å and a minimum thickness of 200Å, which is highly significant in terms of barrier performances.

The following specific examples have been selected as illustrative of various ways in which this invention may be practised. They are not intended to define or to limit the scope of the invention, which is set forth in the appended claims.

In the examples which follow, solute rejection (%) and

flux ( $\text{m}^3/\text{m}^2\text{day}$ ) are calculated as follows:

$$\text{solute rejection (\%)} = (C_1 - C_3)/C_1 \times 100$$

05      Wherein  $C_1$  is the solute concentration in feed and  
          $C_3$  is the solute concentration in the permeate.

$$\text{flux (\text{m}^3/\text{m}^2\text{day})} = Q/S$$

         wherein  $Q$  is the quantity of solvent passing through  
         the membrane per day ( $\text{m}^3/\text{day}$ ), and

10            $S$  is the active membrane surface ( $\text{m}^2$ ).

#### Example 1

15      A polyester woven fabric (taffeta) having a warp density of  
         90/inch and a weft density of 67/inch, and having a thick-  
         ness of 160 micron, woven by using 150 denier multi-  
         filament 20cm by 30cm, was set on a glass plate. A  
         dimethylformamide (DMF) solution containing 16 %  
         polysulfone (Union Carbide Co. Ltd. Udel P-3500)  
20      was applied to the glass plate at a thickness of about  
         200 micron, at room temperature ( $20^\circ\text{C}$ ). The product was  
         immediately immersed in water containing 0.5 % by weight  
         of sodium dodecyl sulphate at room temperature for  
         5 minutes. The product was then washed for 1 hour,  
25      using pure water.

         The resulting fiber reinforced polysulfone substrate  
         (FR-PS) had about 210 micron thickness and had a pure  
         water permeability of 0.005 to 0.001  $\text{g}/\text{cm}^2\text{sec.atm.}$  under  
30      conditions of  $1\text{kg}/\text{cm}^2$  driving pressure and a feed  
         temperature of  $25^\circ\text{C}$ .

         Analysis with electron microscope photographs, showed  
         that the FR-PS possessed 600 pores per square micron,  
35      and each of the pores was between 100 to  $500\text{\AA}$  in diameter.

120 grams of sodium iodide were dissolved in 80 grams of hot methyl ethyl ketone. To this, 92.5 grams of polyepichlorohydrin dissolved in 200 grams of methyl ethyl ketone were added, and the product was stirred at boiling temperature for 25 hours. The resulting solution was cooled to room temperature, filtered and 3000 grams of water were added. The precipitated polymer was washed in 500 grams of methanol and dried in a vacuum at 50°C for 10 hours to obtain a poly-epiiodohydrin. 80 % of the chloro groups were found in chemical analysis to be changed to iodo groups.

12 grams of polyepiiodohydrin were dissolved in 100 grams of tetrahydrofuran and 10 grams of water and 35 grams of 4-(aminomethyl)piperidine were added. After stirring at 35°C for 6 hours, sulfuric acid was added dropwise to neutralize the resultant solution. 300 grams of methanol were added to the resulting solution, and a white precipitate was obtained. This precipitate was purified by use of four reprecipitations, each from a methanol and water solution (methanol/water=3/1). The product was then passed through an anionic ion exchange resin bed to remove the sulfuric acid base, and the polymeric substance was obtained. Infrared spectrum analysis and <sup>13</sup>C nuclear magnetic resonance showed that this polymer was a 4-(aminomethyl)piperidine modified polyepiiodohydrin (polyaminoether).

This polymer was stored in a refrigerator as a water solution. A water solution containing 1.0wt% of the polyaminoether obtained above, 1.2 wt% of m-phenylene diamine and 0.12 wt% of 4-(aminomethyl)piperidine and a trichlorotrifluorethane solution containing 0.05 wt% of trimesoyl chloride were prepared.

05 The water solution was poured on a flat surface of a polysulfone microporous substrate, which was then placed in a vertical position for 30 seconds to drain off the excess solution. After this, the trichloro-  
trifluoroethane-trimesoyl chloride solution was also poured on the substrate on top of the aqueous solution, causing interfacial polymerization to occur. After 30 seconds, the excess solution was drained off in the same manner for 1 minute.

10 The membrane was then cured in a convection oven at 120°C for 10 minutes, crosslinking the water soluble polyaminoether to result in the formation of the intermediate transport layer. It was cooled at room  
15 temperature, and covered by 1 wt% polyvinyl alcohol solution. Excess solution was drained off while maintaining the membrane in a vertical position. The membrane was finally cured at 110°C in an oven for 10 minutes. The reverse osmosis performance of the  
20 resulting composite membrane was measured under the following conditions:

25	Pressure:	56 kg/cm <sup>2</sup>
	Feed solution:	3.5 % NaCl aqueous solution
	Temperature:	25°C

The composite membrane showed 99.4 % salt rejection and 0.54 m<sup>3</sup>/m<sup>2</sup> day water flux.

30 Example 2

35 The microporous polysulfone substrate which was prepared in Example 1 was coated with the aqueous solutions of Example 1 for 2 minutes. The substrate was then placed

in a vertical position for 15 seconds to drain off the excess solution. After this the substrate was coated with the trichlorotrifluoroethane solution containing 0.05 wt% of trimesoyl chloride for 45 seconds. The membrane was cured in a convection oven at 120°C for 10 minutes after drying it in the air for 1 minute. It was cooled at room temperature, and covered by a 2 wt% polyvinyl alcohol solution. The membrane was finally cured at 100°C for 5 minutes. The reverse osmosis performance of the resulting polyamide composite membrane was measured under the following conditions:

	Pressure:	56 kg/cm <sup>2</sup>
15	Feed solution:	3.5 % seawater
	Temperature:	25°C
	pH.	6.5

The composite membrane showed 99.6 % salt rejection and 0.48 m<sup>3</sup>/m<sup>2</sup> day water flux.

After dipping the membrane in the 0.5 wt% aqueous formalin solution at room temperature for 96 hours, the membrane showed the performance of 99.4 % salt rejection and 0.37 m<sup>3</sup>/m<sup>2</sup> day under the same evaluation conditions.

An electron micrograph of the cross-section of the composite membrane shows that this membrane is composed of an intermediate transport layer of about 200Å thickness on the microporous polysulfone substrate, of an ultrathin solute barrier layer of about 300Å thickness and the protective layer, as shown in Figure 1.

Example 3

The microporous polysulfone substrate was prepared by using a DMF solution containing 12 wt% polysulfone according to the same procedure as in Example 1. The preparation of the membrane was otherwise the same as Example 1. The membrane performance of the membrane shows 98.2 % salt rejection and 0.69 m<sup>3</sup>/m<sup>2</sup> day water flux.

Example 4

The composite membrane obtained in Example 1 was tested in the presence of 0.2 ppm chlorine in the feed solution for 2,000 hours under the following conditions;

Pressure: 56 kg/cm<sup>2</sup>  
Feed solution: 3.5 % seawater  
Temperature: 25°C  
pH: 6.5

Test results are shown in table 1.

Table 1

Elapsed time (hrs)	Salt rejection (%)	Water flux (m <sup>3</sup> /m <sup>2</sup> day)
24	99.90	0.35
500	99.90	0.34
1,200	99.87	0.32
2,000	99.85	0.30

Comparative Example 1 and 2

An aqueous solution containing only 2 wt% of m-phenylene diamine was poured on the microporous polysulfone substrate obtained in Example 1 and Example 3, which was then placed in a vertical position for 30 seconds to drain off the excess solution. After this, the trichlorotrifluoroethane solution containing 0.1 wt% of trimesoylchloride was also poured on the substrate on top of the aqueous solution for 30 seconds. The resulting membrane was then dried in air at room temperature. The test results of the reverse osmosis performances are shown in Table 2 under the same conditions as in Example 2.

TABLE 2

Comparative example	Polysulfone substrate	Membrane performances *	
		untreated	treated **
1	Example 1	99.3-0.65	93.0-0.01
2	Example 3	40.0-1.20	-

\* (rejection(%)-flux( $\text{m}^3/\text{m}^2\text{day}$ ))

\*\* treated by the 0.5wt% aqueous formalin solution at room temperature for 96 hours

Example 5

05     Polyethylene imine was used instead of the amine  
modified polyepihalohydrin of Example 1. The  
composite membrane was prepared by the same procedure  
as in Example 1 and tested under the same conditions  
as in Example 1. The test results showed 99.30 % salt  
rejection, and 0.32 m<sup>3</sup>/m<sup>2</sup> day water flux.

10

Example 6 and Comparative Example 3 to4

The composite membranes were prepared by the same  
procedure as in Example 2 or Comparative Example 2,  
except that the factors shown in Table 3 and a mixture  
of trimesoyl chloride and 0.1 wt% of isophthaloyl  
chloride instead of trimesoylchloride were used.  
The ratio of trimesoyl chloride and the isophthaloyl  
chloride is 1 on weight base. Reverse osmosis performances  
were tested under the same conditions as in Example 2.

20

Table 3     -

	Example 6	Comparative example	
		3	4
25     Polyethylene imine (wt %)	1.0	2.0	0.0
m-Phenylene diamine (wt%)	1.0	0.0	2.0
Salt rejection (%)	99.35	85.0	40.0
Water flux (m <sup>3</sup> /m <sup>2</sup> day)	0.35	0.85	1.28

35

- 25 -

Example 7

05     0.2 wt % of polyvinyl alcohol and 0.2 wt% of  
4-(aminomethyl)piperidine were used instead of  
amine modified polyepihalohydrin as in Example 2.

10     The performance of the membrane made from these  
solutions, prepared as in Example 2, was measured  
under the same conditions as in Example 2. The  
membranes showed 98.7 % salt rejection and  
0.42 m<sup>3</sup>/m<sup>2</sup> day water flux.

Comparative Example 5

15     An aqueous solution containing 2 wt% of amine modified  
polyepihalohydrin prepared as in Example 1 and 0.5 wt%  
of 4-(aminomethyl)piperidine was prepared. The composite  
membrane prepared from this solutions and an n-hexane  
20     solution containing 0.2 wt % isophthaloyl chloride  
as in Example 2 were tested under the same conditions  
as in Example 2. The membrane showed 99.6 % salt  
rejection and 0.35 m<sup>3</sup>/m<sup>2</sup> day water flux. After testing  
this membrane under the same conditions as in Example  
4 for 500 hours, the membrane performance changed from  
25     the performance above to 98.6 % salt rejection and  
0.27 m<sup>3</sup>/m<sup>2</sup> day water flux.

35

C l a i m s

1. A high performance semipermeable composite membrane with

(a) a microporous substrate,  
(b) an intermediate transport layer comprising a crosslinked polymer made from a water soluble polymer (x), formed upon and affixed to said microporous substrate,

(c) an ultrathin solute rejection barrier layer comprising (i) an inner portion affixed to said intermediate transport layer and comprising a cross-linked polymer made from the reaction product of a water soluble polymer (x) and a monomer (y) with a crosslinking agent (z), (ii) an outer portion affixed to said inner portion (i) and comprising a crosslinked polymer made from the monomer (y) with the crosslinking agent (z), wherein said water soluble polymer (x) has a reactive amino or hydroxyl groups, said monomer (y) has at least two amino groups on an aromatic nucleus comprising from 1 to 3 aromatic rings, and said crosslinking agent (z) has at least 3 acyl halide groups on an aromatic nucleus comprising from 1 to 3 aromatic rings.

2. The membrane defined in claim 1, wherein said layer (c) has a controlled and substantially uniform thickness of about 100 to 1,000Å.

3. The membrane defined in Claim 1, wherein said water soluble polymer (x) is selected from the group consisting of amine modified polyepihalohydrin, polyethylene imine, polyepiaminohydrin and polyvinyl alcohol.

4. The membrane defined in Claim 3, wherein said amine modified polyepihalohydrin is a modified polymer made by reacting at least one polyepihalohydrin represented by the formula (I);

wherein the X is a halogen selected from the group consisting of Cl, Br and I, and i and j are mole fractions and satisfy the following relationships:

$$i + j = 1$$

$$0.2 < i \leq 1$$

$$0 \leq j < 0.8$$

with at least one monomeric polyamine (II) which is a non-cyclic or cyclic polyamine containing:

- 1) 0 to 1 amino group,
- 2) more than 1 imino group, and in which
- 3) the sum of the amino group and the imino groups is

more than 2, wherein the amino group when present is bonded to a carbon atom and the imino groups are bonded to one to two carbon atoms, the total number of carbon atoms being 3 to 12.

5. The membrane defined in Claim 4, wherein the monomeric polyamine (II) is 4-(aminomethyl)piperidine.

05 6. The membrane defined in Claim 1, wherein the monomer (y) is selected from the group consisting of phenylene diamine, diaminodiphenylether, diaminodiphenylsulfone, diaminodiphenylmethane and tetraaminodiphenylmethane.

10 7. The membrane defined in Claim 1, wherein the said crosslinking agent (z) is selected from the group consisting of trimesoyl chloride and trimellitic acid chloride.

15 8. The membrane defined in Claim 1, wherein said membrane intermediate transport layer has a thickness of about 100Å to 3 microns.

20 9. The membrane defined in Claim 1, wherein said ultrathin solute barrier layer (c) is about 100Å to 1000Å in thickness and said intermediate transport layer (b) is about 100Å to 3 microns in thickness.

25 10. The membrane defined in Claim 1, wherein said microporous substrate (a) comprises an organic polymer selected from the group consisting of polysulfone, chlorinated polyolefin, cellulose acetate and polyvinyl chloride, being optimally reinforced by a material selected from the group consisting of calendered woven fabric, calendered non-woven fabric, uncalendered woven fabric uncalendered non-woven fabric, porous film and paper.

30 11. The membrane defined in Claim 1, wherein the membrane is protected by a crosslinked polymer selected from the group consisting of polyvinyl alcohol, partially saponified polyvinyl acetate, and polyvinyl pyrrolidone.

35

12. The membrane defined in Claim 11, wherein the protective coating has a thickness of about 1000A to about 10 microns.

05 13. A process for producing a high performance semipermeable composite membrane according to any of claims 1 to 12 comprising the steps of:

10 (1) covering the surface of (a) a microporous substrate with an aqueous solution containing at least (x) one water-soluble polymer having reactive amino or hydroxyl groups, said aqueous solution also containing (y) the monomer having at least two amino groups on an aromatic nucleus comprising 1 to 3 aromatic ring (5);

15 (2) covering the resulting coated porous substrate with a solution which is substantially immiscible with the solution of step (1) and which contains (z) a crosslinking agent having at least 3 acyl halide groups on an aromatic nucleus comprising 1 to 3 aromatic rings and being capable of undergoing

20 interfacial polymerization with said reactive groups of the water-soluble polymer and with said monomer to form an ultrathin film on said surface of said microporous substrate;

25 (c) continuing said interfacial polymerization reaction for a time sufficient to cause migration of at least a portion of said monomer through the inner portion of the ultrathin film, thereby reacting with said crosslinking agent to form an outer portion of the ultrathin polymeric layer on the inner portion of the

30 ultrathin layer being formed; and

(d) drying the resulting composite semipermeable membrane at elevated temperature for a time sufficient to crosslink said water-soluble polymer.

05 14. The process defined in claim 13, wherein the aqueous solution contains a mixture consisting of about 10 % to about 90 % by weight of the water soluble polymer and of about 90 % to about 10 % by weight of the monomer.

10 15. The process defined in Claim 13, wherein the concentration of the aqueous solution is in the range of about 0.1% to 10% by weight.
